

HOW TO PUBLISH YOUR QUARTO WEBSITE ON GITHUB PAGES (Lab X Guide)

By: Renu Madhuraj Jadhav

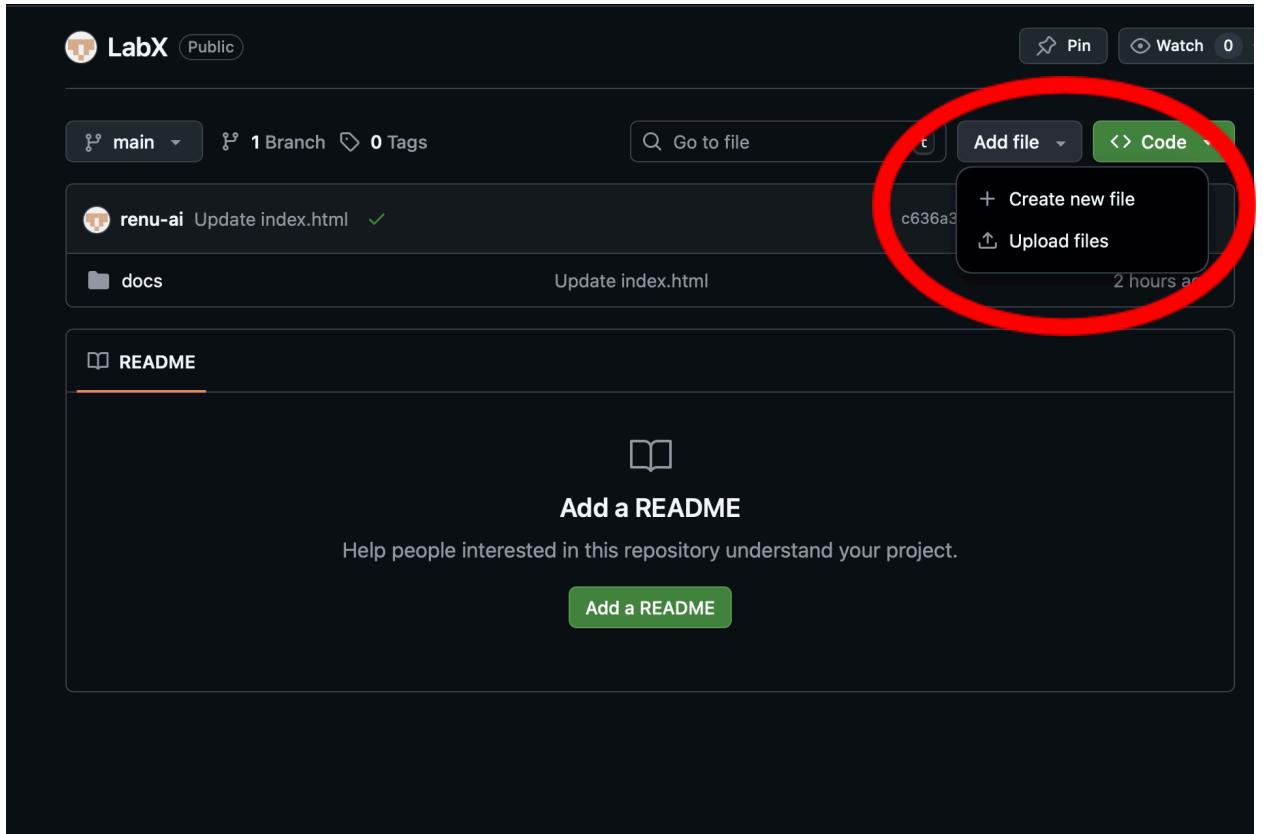

1. Set up your repository

- a. Create a new GitHub repo. Just click on the green button that says “New”. Name it whatever you want.

b.

- c. Make it **Public** (Pages does *not* work on private repos unless you pay)

d. Upload your files. Drag and Drop works the best.

e. Commit your changes.

Important: Put your website files in the *root*.

Do NOT place them inside another folder like `LABX/`. GitHub Pages will NOT find
`/docs`.

2. Configure your Quarto project

In your main `.yml` file, set:

```
project:  
  type: website  
  output-dir: docs
```

Quarto normally outputs to `_site/`, but GitHub Pages only works with a folder named **docs**.

```
1 - project:
2   type: website
3   output-dir: docs
4
5 - website:
6   title: "Renu Madhuraj Jadhav"
7   description: "Computational Health Researcher – Exploring the intersection of AI and medici
```

3. Render your website locally

Either pick the “ Save to Render” option or in RStudio terminal type:

```
quarto render
```

This creates the folder:

```
docs/
  file1.html
  file2.html
  file3.html
  File4.css
```

If you do not see a `docs/` folder → your site will NOT deploy.

4. Upload the `docs` folder to your repository.

Make sure you do not have any `_sites` files in your repository already. Remove them before uploading your `docs/` folder. DO NOT delete anything from the `docs` folder.

5. Fix the biggest GitHub Pages issue

GitHub Pages by default tries to run **Jekyll**.

Quarto sites are **NOT** Jekyll sites.

You **MUST** disable Jekyll, otherwise GitHub will crash.

Inside your `docs/` folder(that you uploaded in your repo), pick the “create a file” option and name the file:

```
.nojekyll
```

Leave it empty.

REMINDER:

5. Delete the `_site/` folder.

Again:

If you ever rendered your site before changing `output-dir`, you will have: `_site/` folder.

GitHub Pages **does not care** that it's not being deployed.

If GitHub sees *any folder starting with _*, it **forces Jekyll mode** and breaks everything.

So delete `_site/` completely.

7. Commit the changes:

Make sure you have these items:

- `docs/` (HTML, CSS, images, `.nojekyll`)
- all your `.qmd`
- `.yml file` that you created

Do **NOT** push your entire Quarto folder *inside* another folder.

8. Enable GitHub Pages

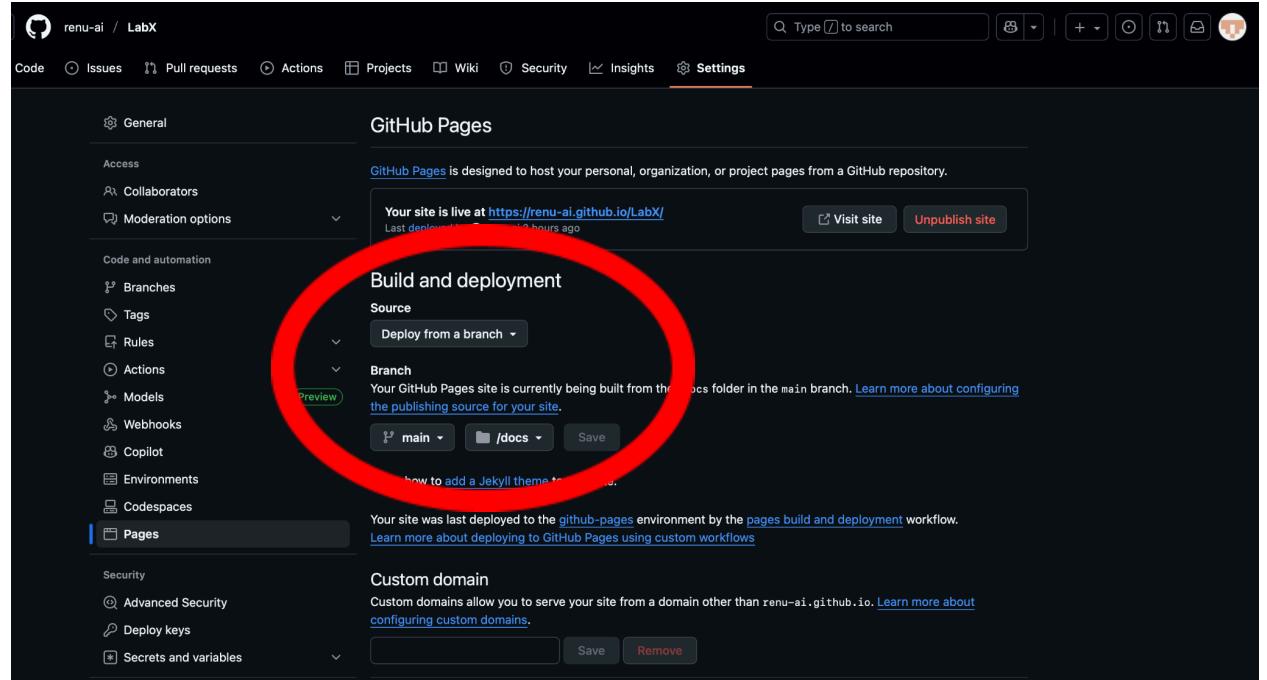

Go to your repository:

`Settings → Pages`

Set:

- **Source:** Deploy from a branch
- **Branch:** main
- **Folder:** /docs

Save.

After 30–60 seconds, your site will build.

9. Understanding build errors (this helps a LOT)

Check the email associated with your github account.

You might see errors like:

1. Build fails with: No such directory @ dir_chdir - /github/workspace/docs → Your docs folder is not in the root. Move it out of subfolders.
2. Build fails with SCSS error: Error: Rendering assets/css/style.scss → You forgot .nojekyll or you still have _site/.
3. Deploy step shows: Canceling Pages deployment failed → This is harmless. Your site is already deployed.

10. Your website link:

Once deployed, GitHub will show:

<https://YOUR-USERNAME.github.io/REPO-NAME/>

THAT IS ALL!!!! Yay.
